

# Data Quality & Validation Log

Sales Forecasting & Revenue Trend Analysis

| Check                   | Method                                                   | Result                                                   | Action Taken                                     |
|-------------------------|----------------------------------------------------------|----------------------------------------------------------|--------------------------------------------------|
| Completeness            | Checked all 100 rows across 14 source columns for blanks | No blanks found                                          | None needed                                      |
| Duplicate Order IDs     | Counted unique values in Order ID vs. total rows         | 100 unique IDs, no duplicates                            | None needed                                      |
| Revenue = Units × Price | Recalculated Revenue for every row                       | All 100 rows matched                                     | None needed                                      |
| Profit = Revenue – Cost | Recalculated Profit for every row                        | All 100 rows matched; margins 25–40%, realistic for FMCG | None needed                                      |
| Date range validity     | Confirmed dates fall Jan 2024–Dec 2025                   | All in range, ~4 orders/month                            | None needed                                      |
| Negative/zero values    | Scanned all numeric columns for values $\leq 0$          | None found                                               | None needed                                      |
| Category consistency    | Checked each product maps to one category only           | Consistent throughout                                    | None needed                                      |
| Outlier scan (variance) | Flagged rows with >20% actual-vs-forecast gap            | 1 case: ORD-1041, festive bulk order (175 units)         | Kept; flagged as genuine demand spike, not error |

## Overall Conclusion

The dataset passed all structural and arithmetic checks with no corrections required. This reflects a clean source system; in a live environment I would expect to spend meaningfully more time here. The one item worth flagging to stakeholders is the reliance on only 24 months of history, which limits how confidently any seasonal or trend pattern can be generalized. This is a data sufficiency issue, not a data quality issue, and has been carried into the forecasting model's risk notes.
